For Lab 3 I first drew the A to G graph on paper and then wrote BFS with a queue and DFS with a stack, and my DFS first went the wrong way because I did not reverse the neighbours, so after fixing that I got A, B, D, E, G, while BFS gave A, B, C, D, E, F, G, and both ended at the same path A, B, E, G. Next I tried DLS at limits 1, 2, 3 and 4, and the first two only gave a cutoff, which I first read as no path, but limit 3 found G, and IDDFS found it at the same limit after trying 0, 1, 2 and 3 again, and I also learned not to use one visited set for all limits. At the end I made the weighted graph with the costs written in the code, and UCS gave A, B, E, G for 3, while BFS on the same graph gave A, C, G for 12, so I saw that fewer steps do not always mean less cost.
